Organisational aspects of elder mistreatment in residential care

Abstract

Purpose

This paper examines organisational aspects of elder mistreatment in light of the findings of the ResPECT Study of Organisational Dynamics of Elder Care commissioned by Comic Relief and Department of Health through the Prevention of Abuse and Neglect In the Care of Older Adults (PANICOA) programme. The study examined the organisational factors associated with abuse, neglect and/or loss of dignity of older people resident in care homes.

Approach

The study involved a knowledge synthesis of organisational aspects of elder mistreatment in residential care settings. The knowledge synthesis method was purposively adapted for examining the ill-defined and contested concept of elder mistreatment, as the available evidence is in varied forms and dispersed. Extensive searching of databases of academic journals was combined with careful searching for official investigation reports into mistreatment. The review and synthesis was followed by panel meetings with subject matter experts.

Findings

This paper identifies and elaborates five organisational factors associated with elder mistreatment; infrastructure, management and procedures, staffing, resident population characteristics and culture. It also indicates macro-structural factors affecting care quality. Investigation reports recognised common structural factors contributing to institutional abuse, however, as ‘problem’ organisations are closed down these circumstances recur elsewhere.
Research implications

Further work is needed to understand the interaction between and the influence of these organisational factors on mistreatment.

Practical implications

This may go some way towards explaining how care quality can collapse as a result of seemingly minor and unrelated organisational changes.

Social implications

Care home safety and quality is an ongoing concern, with popular analysis frequently stopping at the point of describing individual errant behaviour. Policy and practice struggles to take on lessons learned in inquiries. This synthesis deepens analysis of the inter-related factors.

Keywords: elder abuse, neglect, mistreatment, organisation, residential care, institutional abuse, older people

Introduction

This article identifies and elaborates organisational aspects of elder mistreatment in residential care settings (* 2012). The article uses findings from a knowledge synthesis which comprised a review of the literature on mistreatment, examination of investigation reports into incidents of abuse in long-term care settings and panel meetings with subject matter experts – residents, relatives, care staff and managers of residential care homes.
The problem of care quality for older people is an enduring theme in public policy writing. However, there has been limited research into elder abuse, generally (see Daly, Merchant and Jogerst 2011 for a systematic review), and even fewer studies of residential care settings. A recent study suggests that those in residential care report better wellbeing than those at home (Böckerman, Johansson and Saarni 2011). Nevertheless, there is a public perception that mistreatment is commonplace in institutional care (Hussein, Manthorpe and Penhale 2007). Reports of institutional mistreatment occur at regular intervals in the media (British Broadcasting Corporation 2014, Action on Elder Abuse 2006). In fact, there has been active policy development in recent years in respect of funding, regulation, quality assessment and safeguarding, with, for example review of regulatory procedures (CQC 2013) and review and public consultation on adult safeguarding statutory guidance (DoH 2011).

Abuse, neglect and loss of dignity have proven difficult concepts to define, nevertheless, categories of mistreatment have been described and include; physical abuse, psychological abuse, active and passive neglect (Dixon et al. 2010). Studies have also indicated a dearth of information about the prevalence of mistreatment of older people in institutional settings linked to a lack of consistency in reporting (Manthorpe et al. 2011). Whilst little is known about the prevalence of mistreatment of older residents, a study of residential care staff in the U.S. indicated that 36% of staff had witnessed abuse in the previous 12 months, the most common form being shouting (Pillemer and Moore 1989). A further U.S. study indicated that 44 per cent of residents reported abuse and 48 per cent reported having been handled roughly (Atlanta Long Term Care Ombudsman Program 2000).

There has been some research on the underlying causes of negative behaviours in organisational settings. Furnham and Taylor (2011) categorised the underlying causes as;
‘intra-personal’ (bad people), inter-personal (bad groups and bad management) and
‘organisational’ (counter-productive organisational structures). The third category
incorporates the idea that organisational arrangements affect how people go about their work.
Rather than excusing bad behaviour this categorisation enables a more detailed understanding
of contributory factors. This paper focuses on organisational factors as an adjunct to intra-
and inter-personal categories. We use the term ‘organisational factor’ to delineate aspects of
organising care provision and the term ‘organisational dynamics’ to mean interactions
between organisational factors.

Synthesis of knowledge

Methods for reviewing the literature on subjects as diffuse as the relationship between
organisational factors of mistreatment are relatively underdeveloped. Drawing on methods of
scoping reviews and knowledge synthesis (Anderson et al. 2008, Petticrew and Roberts 2005,
Pope, Mays and Popay 2007, Thorne et al. 2004, Walsh and Downe 2005), we examined the
organisational factors associated with the abuse, neglect and/or loss of dignity of older people
in residential settings. This involved two types of work: firstly a focused, quasi-systematic,
literature review examining recent research and grey literature and inquiry reports for both
theoretical and empirical advances; and secondly discussion of emerging findings from the
literature review with two panel groups of experts – providers and service users.

Methods

Methods used for similar reviews were followed by examining social science theories, recent
research, grey literature and investigation reports (Ferlie and McGiven 2003; Pope, Mays and
Popay 2007). There was a limited range of literature available for review and the challenge
was to ensure that the review had sufficient depth and breadth of coverage. Search terms such
home ‘older people’ were used in searching the available literature through health, social science and management databases (Health Management Information Consortium -HMIC, Psychinfo and Web of Science). However, the most fruitful means of accessing empirical studies was achieved by tracking citations arising from the small number of empirical studies available (Pope, Mays and Popay 2007). Additional search materials were identified, such as, policy documents, inquiries, investigations and grey literature (for more detail see * 2012). References from two anthologies of research reports on elder abuse were also retrieved (Bonnie and Wallace 2003; Bennett, Kingston and Penhale 1997). The results from multiple searches were merged and duplicate records removed. Titles and abstracts were reviewed and obviously irrelevant reports and papers were excluded (Petticrew and Roberts 2005). Full text copies of remaining papers and reports were retrieved and examined against eligibility criteria, i.e. relevance to the study of organisational aspects of mistreatment of older people living in residential care or nursing homes. Inquiry reports into institutional abuse in hospital settings were included as well as reports concerned with residential and nursing homes, because of the limited evidence about institutional abuse. Firstly, the review identified the major schools of thought about elder mistreatment to ensure a broad range of disciplinary perspectives were included (Booth cited in Petticrew and Roberts, 2005:72). Secondly a data extraction template was used to record details of mistreatment, organisational aspects involved and the place of study. A narrative synthesis approach was used to synthesise the findings (Petticrew and Roberts 2005). The resultant records were organised into logical categories. A within-study analysis was carried out using content analysis, identifying ten categories. A cross-study analysis was then used to summarise the evidence into five key organisational factors – organisational infrastructure, management and procedure, staffing, resident characteristics and organisational culture. A supplementary category for macro-structural factors was also created.
The key factors of organisational mistreatment identified through the narrative synthesis were presented to service user and service provider panel groups (subject matter experts) and their responses were incorporated into the findings. The study aimed to examine the organisational aspects of mistreatment (including abuse, neglect and/or loss of dignity) of older people resident in care homes. The findings are presented below and begin with a brief summary of theoretical perspectives on elder mistreatment before recent investigation reports are outlined. Each of the organisational factors related to mistreatment in residential care are elaborated.

**Theoretical perspectives on elder mistreatment**

Whilst mistreatment of older people in institutional settings has been relatively under-theorized, certain social science disciplines indicate means of theorizing organisational aspects of the phenomenon. Social science perspectives draw attention to both macro- and micro-sociological factors which would contribute in a systemic way to poor quality care. Research in the organisation studies tradition highlights how care quality is affected by organisational arrangements and has focused attention on structural arrangements for providing care, illustrating how organisational arrangements can enhance or inhibit an individual’s capacity to care. Alternatively, psychological perspectives have been important in explaining how workers may come to mistreat those who depend upon them (Campbell Reay and Browne 2002). One approach is concerned with individual characteristics of abusers and the abused while another focusses on stress models and the interaction between the abuser and their environment. Sociological approaches focus on the social circumstances for institutional care provision. They identify a paradox between institutions offering care whilst also appearing to punish age-related dependency. By contrast, social policy
perspectives assume that institutional care systems will be inherently benign with abuse occurring as an aberration correctable through regulation and review of individual actions (Wardaugh and Wilding 1993) omitting societal, structural and organisational factors. More recently Schiamberg et al. (2011) presented an ecological perspective on elder abuse in nursing homes. This approach argued that abuse occurs in a micro-systemic context. Instead of focusing on individual factors as risk factors, they argue for the need to study the dynamic interactions between individuals and contextual factors.

In summary, there is little convergence of theoretical work in relation to mistreatment in residential care organisations and yet, the common and repeated sets of circumstances behind residential care scandals suggest that work in this area would be valuable.

**Contemporary investigations into institutional mistreatment**

In the UK, public inquiries investigate the circumstances surrounding organisational failures such as mistreatment of residents. As such, they provide detailed analyses and offer publically available accounts of the circumstances surrounding these events. A review of UK investigation reports over a 40 year period found that many highlighted similar, repeated sets of circumstances leading to failures in care (Walshe and Higgins 2002). Moreover, public investigation reports have consistently reported similar sets of circumstances and have made similar recommendations (CHI 2004a, CHAI 2009) [See Note 1] despite fundamental changes to the management, regulation and structure of care services, including the closure of long stay hospitals and the creation of regulatory bodies such as the Care Quality Commission (CQC). This repetition of findings is highlighted by the similarity between two reports published 20 years apart. Martin (1984) compared the findings of inquiries into allegations of abuse within hospitals from 1969 to 1980 and identified ten broad themes
encapsulating hundreds of findings and recommendations. A subsequent report (CHI 2004a),
examining the eleven investigations published between 2000 and 2003, identified eight
recurrent themes, namely; severe staff shortages, ineffective risk management, lack of agreed
policies, supervision of staff and audit, poor team relationships, inadequate leadership,
financial problems and a tendency for the service to be geographically or clinically isolated.
In addition to these organisational factors the review of investigations identified risk factors
at strategic and national/policy levels, such as, recent restructuring, failure to deal with earlier
complaints and low priority services. These reports described repeated sets of social
circumstances which relate to organisational arrangements for care provision, without
exploring how these factors interacted in long-standing failures of care.

Historically, institutional abuses have tended to be conceived of as ‘isolated events’ and the
individuals concerned as ‘rotten apples’ who wilfully or negligently failed in their duty of care.
This approach is argued to have drawn attention away from examining organisational and system-
wide structures within which such abuses took place (Manthorpe and Penhale, 1999).

The publication of the first public inquiry by the Commission for Health Improvement (CHI)
in 2000, marks the beginning of a number of contemporary public inquiries in the UK. We
searched CHI and CSCI reports from 2000 onwards as these follow the closure of long stay
hospitals, the introduction of the Community Care Act (1990) and the establishment of new
national regulatory bodies. Nine reports were selected because they involved allegations of
institutional abuse toward vulnerable adults and older people within in-patient and residential
care facilities:

1. Investigation into mistreatment of elderly patients at North Lakeland NHS Trust (CHI
   2000:1).
2. Investigation following a police investigation into suspicious deaths of five older people at Portsmouth Healthcare NHS Trust (CHI 2002:vii)

3. Investigation into residential services for people with learning disabilities at Bedfordshire and Luton Community NHS Trust (CHI 2003a).

4. Investigation into the care of older people on Rowan Ward at Manchester Mental Health and Social Care NHS Trust (CHI 2003b:2).

5. Investigation into acute, community and mental health services at Pembrokeshire and Derwen NHS Trust (CHI 2004b).

6. Investigation into care of people with learning disabilities at Cornwall Partnership NHS Trust (CHA 2006).

7. Investigation at Sutton and Merton NHS Trust in one hospital and three community homes (CHA 2007).

The findings and recommendations from these investigations indicated repeated institutional failures to properly care for vulnerable adults and older people. They found several commonly-identified problems including an increase in the number of high dependency residents, lack of capability of staff, poor staffing levels, the use of immigrant staff with little command of English and a lack of policy and guidelines and/or their proper implementation and monitoring. What is notable is that seemingly minor or relatively common changes were leading, at times, to spectacular failures of care. Hence, these investigations identified problems and concerns for the way health and social care services were organised and delivered. In addition there were incidents of repeated failure, where one or more people were
found to be regularly physically abusing residents, triggering or resulting in the suspension and/or disciplining of particular staff members. The reports recommended the referral of these individual staff members to the national council of nursing for possible competence review of their practice. At Rowan Ward in England and the Leas Cross Nursing Home in Ireland, the facilities were subsequently closed down.

Organisational aspects of mistreatment

Several commonly occurring organisational factors were associated with sustained reduction in care quality: infrastructure, management, staffing, resident population characteristics and culture. They are elaborated alongside reference to the source material.

1. Infrastructure

Organisational infrastructure refers to the physical environment, building design and architecture, the general upkeep of the building, provisions for catering, cleaning and maintenance. Mistreatment of older people was found to have taken place in residential settings where there were run-down facilities, cramped conditions (Hawes 2003), overcrowding of residents, lack of equipment and generally poor physical environments (Wiener and Kayser-Jones 1990, CHI 2004b). One study concluded that large-sized units promoted regimentation and negatively affected individualised care (Wardhaugh and Wilding 1993). Provisions for catering, cleaning and maintenance that were found to be problematic included poor catering provision and food hygiene (CHAI 2009), unchanged bed linen, strong odours of urine/faeces (Lindbloom et al. 2005), and a lack of privacy with open bathing, toileting and washing (Bennett, Kingston and Penhale 1997). Investigations found that poor
conditions in these particular residential settings were reoccurring problems that had been well documented in the past.

2. **Management and procedures**

Management, for the purpose of this study, refers to: management arrangements, systems and practices, leadership, supervision, organisation and support of staff. Procedures refer to the systems in place for carrying out actions in caring for older people in residential care, including written policies and procedures. Poor management and/or leadership has been identified as a key factor of institutional mistreatment (Bennett, Kingston and Penhale 1997, CHAI 2009, CHI 2004a). Investigations suggested that problems arose over a substantial period of time with little effective response to concerns being raised (CHI 2004a). Problems associated with changes in unit managers included; not having a manager in place, little continuity of management, lack of leadership, poor quality management and lack of a permanent manager in post (CHAI 2006, CHI 2003b). Overly bureaucratic and instructive management styles were associated with mistreatment, alongside a lack of investigation into complaints or failure to take actions following the outcome of previous investigations (Wardhaugh and Wilding 1993). A range of inadequate policies were found in five of the investigations of institutional abuse and neglect in the UK, including policies on complaints, protection, the use of restraint, the management of incontinence, the management of medicines and the provision of palliative care (Bennett, Kingston and Penhale 1997, CHI 2004a, CHAI 2009).

Members of the provider panel argued that a ‘no blame culture’ for mistakes that may occur was important as mistakes and practices of sub-standard care were more likely to be
acknowledged and reported and therefore rectified, if staff were sure they would not be blamed individually for the problems.

Members of the service user panel said that residents would be very reluctant to disclose abuse, neglect or poor care as they would fear that this would lead to the closure of the home. The closure of the home, and the upheaval of finding and moving to another home was a daunting prospect.

Specific additional management problems included unclear lines of accountability (CHAI 2006), the absence of monitoring and supervision of services and staff; absence of staff appraisal and support and poor judgement when recruiting new employees (Buzgová and Ivanová 2009). In addition, poor, inconsistent or falsified record keeping was notable as was poor collection and use of information on outcomes of care (CHAI 2009).

The service provider panel group argued that relationships were important and saw the leadership offered by managers as playing an important role. Panel members associated factors of respect and dignity with an absence of overly-rigid routine; the provision of ongoing training; and access to sources of support for all staff including home managers and owners.

3. **Staffing**

Factors related to staffing were a commonly-identified theme within research studies, reports and investigations into mistreatment and included; inadequate staffing levels and staff shortages (CHI 2004a), extensive use of temporary or short-term staff (CHI 2003a, CHI 2003b) and high staff turnover (Lee-Treweek 1997). Staff were found to be working long hours and subject to mandatory overtime leading to tired staff (Hawes, Blevins and Shandley...
2001), high workloads (Global Action on Aging 2009) and low morale (CHAI 2007). Further problems related to inadequate staff skill mix (Bennett, Kingston and Penhale 1997), limited ability in English language (Wiener and Kayser-Jones 1990) and lack of competency (Teeri, Leino-Kilpi and Välimäki 2006). Some staff were unable to recognise abuse and had negative attitudes towards patients (CHAI 2007). Much of the work in this area identified lack of staff training as an issue (Bennet, Kingston and Penhale 1997, CHAI 2009). Individual characteristics of staff included alcohol dependency (Bennett, Kingston and Penhale 1997), childhood experiences of abuse and high anxiety (Campbell Reay and Browne 2001) and state of anger scores (Gates, Fitzwater and Meyer 1999). One study found too much staff autonomy contributing to mistreatment (Bennett, Kingston and Penhale 1997).

The quality of relationships between staff and residents was important to both user and provider panel groups and the organisation of staff, including the lengths of shifts, the number of people on duty, and the consistency and continuity of the staff group all played an important part in the development of relationships. Residents valued being known as individuals, and also, in return, knowing staff as people with broader lives. For resident members of the user panel, the concept of respectful care included sharing some of the responsibility for the day-to-day running of the home.

4. Resident population characteristics

Specific characteristics associated with mistreatment include the type and level of dependency, complexity of care needs and residents’ own behaviour. The findings suggest that residents were at risk where they, or their relatives, had limited awareness of how to assert their rights and limited access to personal, individual choices (CHAI 2009). Moreover, investigations found that an increase in the proportion of high dependency patients could lead
to mistreatment (Buzgová and Ivanová 2009, Commission of Investigation 2009). Specific characteristics associated with mistreatment included residents with high levels of dependency, cognitive impairment or dementia (Burgess, Dowdel and Prentky 2000), physically aggressive or uncooperative behaviour (Buzgová and Ivanová 2009) and passivity, introversion or frailty (Wardaugh and Wilding 1993). Indicators of mistreatment of residents included; unexplained deaths and injuries, dramatic weight loss (Commission of Investigation 2009), untreated or poorly treated pressure ulcers (Pillemer and Bachman-Prehn 1991), oversedation and missing property (Commission of Investigation 2009).

Both panels were concerned about what may happen when the needs of residents change. There needs to be a fit between the needs of the group of residents and the adaptability of the home. The literature review showed that quickly changing levels of need, along with a concentration of people with high levels of need could destabilise the care provision in a home. Discussion with the panel groups showed achieving a good fit is problematic as it is potentially highly distressing for a resident whose need for support increases to have to leave a home, with all the implications for loss of existing relationships with staff and having to get to know a completely different group of staff. The provider panel group particularly highlighted the issue of block contracts which could further reduce flexibility.

5. Culture

Culture was taken to entail practices shaped by shared beliefs and expectations among staff and other groups, which, in turn, produced norms that influence the behaviour of both staff and residents. Aspects of culture associated with mistreatment included isolation either geographically or socially with limited official or social visitors (CHI 2003b). Such organisations were found to have closed, inward-looking cultures with managers and/or staff
who were institutionalised and closed off to possibilities for change (CHI 2004a). There was a focus on external targets, bureaucracy or standardised rather than individual care (Bennett, Kingston and Penhale 1997). This gave rise to overly-bureaucratic or autocratic culture that left staff with little control over their work situation and no say about how work was organised (Buzgová and Ivanová 2009). Poor communication (Wiener and Kayser Jones 1990) and factions among the staff (CHI 2004a) were also features of the local culture. Entrenched routines were seen to objectify residents (CHAI 2009) and there was a lack of renewal of expectations and new ideas (Wardaugh and Wilding 1993).

Service users emphasised contact with the outside community as vital to their wellbeing. Residential care that involves and supports a good level of integration with the local community and where there is on-site involvement of allied service providers such as social workers and doctors were also identified, by panel groups, as factors contributing to respect and dignity.

6. Macro-structural factors

Macro-structural factors were things that affected the organisation and related to wider social arrangements for residential care for older people. They are included here as they have a direct impact on care provision. Significant organisational changes such as, major structural changes, restructuring, and changes in ownership were associated with episodes of mistreatment (CHI 2004a). Reduced support from the wider organisation was indicated in one investigation report (CHI 2003b). Financial pressures were also mentioned frequently, particularly efficiency savings, reduced financial provisions and lack of resources to provide adequate care (Bennett, Kingston and Penhale 1997). A focus on high profile targets was
shown to re-direct resources and attention towards meeting targets rather than the immediate
needs of staff and residents (Joint Committee on Human Rights 2007).

Alongside ambiguous accountability arrangements in the wider care community (CHI 2004a), ineffective monitoring by external agencies and failure to challenge punitive care
systems was also cited (CHAI 2006). In addition, there were cases where the nature of the
relationship with overseeing bodies such as an NHS Trust or social services were said to
contribute to the escalation of mistreatment. This included reduction in support and
ineffective monitoring by external bodies (CHI 2003b, CHI 2004a).

Organisational aspects of mistreatment in residential care

In most of the material reviewed, the organisational factors associated with mistreatment
were found to exist in combinations of two or more factors. Hence, the factors represent
commonly-occurring and cross-cutting factors linked to organisational failure to prevent
mistreatment. Importantly, small changes that took place within a home (and to the wider
organisational context within which it was placed) could, at certain times, lead to a spiral of
declining care. If one factor changes within a system, it will have an impact on the overall
system and its capacity to deliver good quality care. The studies reviewed suggested that the
quality of care was being driven by interactions between individual actors, organisational
factors and macro-structural factors.

Systems theory has been used to examine organisations as it allows consideration of
interactions and processes with multiple and non-linear effects (Hatch and Cunliffe 2006).
The behaviour and actions of all those involved in the organisation (e.g. residents, staff,
relatives, owners) and also the context of the organisation (e.g. social, financial, physical)
interact dynamically in what could be considered a complex system (Cilliers 2005). Cilliers
argues that the system will organise itself to be sensitive to events that are critical to its
survival. In other words, relationships between causes and effects are not straightforward and may be either amplified or minimised through dynamic interactions.

There have been several calls for the development of an early warning system to highlight the risk of serious failure (CHI 2004a:2, CHAI 2009:42). This study addresses the fact that ‘there is little or no data on risks to the safety of patients which are not incidents’ (CHAI 2009:32) by enhancing understanding of organisational causes of abuse (Furnham and Taylor 2011). Further research is needed to develop understanding of interplay between organisational factors.

Conclusions

This study identified and elaborated five interrelated organisational factors important in understanding mistreatment of older people in residential settings; organisational infrastructure, management and procedures, staffing, resident population characteristics and culture as well as delineating macro-structural factors. It was notable that relatively small organisational changes in one or more of these areas could cause care quality to decline rapidly. It is not enough to close down failing organisations, not least because inquiry reports illustrated how repeated sets of circumstances led to similar failures elsewhere. Understanding the links between organisational systems and care quality will be important as demands for residential care continue to grow and the availability of funding remains limited.

Given the interdependence of systemic and organisational factors of care service provision, the maintenance of respect and dignity will require individual, organisational and policy level interventions. For research to be effective and useful, a better understanding of how organisational factors affect care quality is required. Future research into elder mistreatment might usefully examine the interplay of organisational factors in residential care in order to elaborate how they affect care quality in practice and how they contribute towards sustaining robust systems of care even when circumstances may change.
Statement of ethical approval

The study was reviewed by Cambridgeshire 3 NHS Research Ethics Committee (ref 09/110306/63).

Notes

1. The regulatory body responsible for inspecting NHS organisations has undergone several name changes. Currently known as the Care Quality Commission (CQC), previously known as the Health Care Commission (HCC), Commission for Health Improvement (CHI), Commission for Healthcare Audit and Inspection (CHAI).

Organisational aspects of elder mistreatment in long term care

Abstract

Purpose

This paper proposes five organisational factors associated with abuse, neglect and/or loss of dignity of older people resident in care homes. It derives from one set of findings from the ResPECT Study of Organisational Dynamics of Elder Care commissioned by Comic Relief and Department of Health through the Prevention of Abuse and Neglect In the Care of Older Adults (PANICOA) programme.

Approach

A knowledge synthesis method was selected to identify organisational aspects of elder mistreatment in residential care settings. The method was selected for its suitability in examining ill-defined and contested concepts such as; elder mistreatment - where the available evidence is dispersed and produced in varied forms. A rapid review comprising a search of three academic databases and a detailed examination of selected investigation reports into institutional mistreatment was followed by panel meetings with subject matter experts to complete the knowledge synthesis.

Findings

This paper identifies and elaborates five organisational factors associated with elder mistreatment; infrastructure, management and procedures, staffing, resident population characteristics and culture. It also indicates macro-structural factors affecting care quality.

Research implications
Further research is needed to elaborate the influence of these organisational factors on mistreatment and to understand any interactions.

**Practical implications**

As an adjunct to personal factors, the knowledge synthesis indicates common organisational factors contributing to institutional abuse. This suggests that care quality is produced systemically and that it can collapse as a result of seemingly minor and unrelated organisational changes.

**Social implications**

Care home safety and quality is an ongoing concern, with popular analysis frequently stopping at the point of describing individual errant behaviour. However, as ‘problem’ organisations are closed down, ‘problem’ organisational factors continue to recur elsewhere.

**Keywords:** elder abuse, neglect, mistreatment, organisation, residential care, institutional abuse, older people

**Introduction**

This article identifies five organisational factors associated with abuse, neglect and/or loss of dignity of older people resident in care homes. These factors arise from a knowledge synthesis which comprised a rapid review – a search of literature on mistreatment in residential care settings and investigation reports into abuse in long-term care settings - and panel meetings to examine the review findings with subject matter experts (care staff, care home managers, relatives and residents).
Although research suggested that those in residential care report better wellbeing than those at home (Böckerman, Johansson and Saarni 2012) there is a public perception that mistreatment is commonplace (Hussein, Manthorpe and Penhale 2007) and reports of institutional mistreatment occur at regular intervals in the media (British Broadcasting Corporation 2014, Action on Elder Abuse 2006). Moreover, while care quality for older people is an enduring theme in public policy there has been limited research generally into elder abuse (see systematic review by Daly, Merchant and Jogerst 2011) and even less in residential care settings. Nevertheless, recent policy developments following, for example, a review of regulatory procedures (Care Quality Commission 2013) and public consultation on adult safeguarding (Department of Health 2011) have included changes to funding, regulation, quality assessment and safeguarding.

Abuse, neglect and loss of dignity have proven difficult concepts to define. Nevertheless, categories of mistreatment have been described and include; physical abuse, psychological abuse, active and passive neglect (Dixon et al. 2010). Studies have also indicated a dearth of information about the prevalence of mistreatment of older people in institutional settings linked to a lack of consistency in reporting (Manthorpe et al. 2011). Whilst little is known about the prevalence of mistreatment of older residents, a study of residential care staff in the U.S. indicated that 36% of staff had witnessed abuse in the previous 12 months; the most common form being shouting (Pillemer and Moore 1989). A further U.S. study indicated that 44 per cent of residents reported abuse and 48 per cent reported having been handled roughly (Atlanta Long Term Care Ombudsman Program 2000).

Furnham and Taylor (2011) proposed three underlying causes of negative behaviours in organisational settings; ‘intra-personal’ (bad people), ‘inter-personal’ (bad groups and bad
management) and ‘organisational’ (counter-productive organisational structures). The third
category indicates that organisational arrangements affect the way that people do their jobs.
Rather than excusing bad behaviour this categorisation enables a more detailed understanding
of contributory factors. This paper focuses on organisational factors as an adjunct to intra-
and inter-personal categories. We use the term ‘organisational factor’ to delineate aspects of
organising care provision.

Knowledge synthesis

Methods for reviewing ill-defined and diffuse concepts such as elder mistreatment are
relatively underdeveloped. However, knowledge synthesis is emerging as effective means of
analysis in these circumstances (Anderson et al. 2008, Petticrew and Roberts 2005, Pope,
Mays and Popay 2007, Thorne et al. 2004, Walsh and Downe 2005). We took this approach
to examine the organisational factors associated with the abuse, neglect and/or loss of dignity
of older people in residential settings. The knowledge synthesis involved two types of work:
firstly, searching for theoretical and empirical advances through a rapid review of recent
research and grey literature and inquiry reports and, secondly, analysis of emerging findings
with subject matter experts (Ferlie and McGiven 2003; Pope, Mays and Popay 2007).

There was a limited range of literature available for review and the challenge was to ensure
that the review had sufficient depth and breadth of coverage. Three social science and
management databases (Heath Management Information Consortium -HMIC, Psychinfo and
Web of Science) were searched using the following terms; ‘abuse’, ‘neglect’, ‘mistreatment’,
‘institutional care’ ‘care facility’ ‘care home’ ‘nursing home’ ‘older people’. The results of
these searches are summarised under ‘Organisational aspects of mistreatment’ below.
However, it should be noted that the most fruitful means of accessing empirical studies was
achieved by tracking citations arising from the small number of empirical studies available (Pope, Mays and Popay 2007). Additional search materials were identified, such as, policy documents, inquiries, investigations and grey literature (for full details see * 2012).

References from two edited collections of research into elder abuse were also retrieved (Bonnie and Wallace 2003; Bennett, Kingston and Penhale 1997). The results of these multiple searches were merged and duplicate records removed. Titles and abstracts were reviewed and obviously irrelevant reports and papers were excluded (Petticrew and Roberts 2005). Full text copies of remaining papers and reports were retrieved and examined for relevance to the study.

Inquiry reports into institutional abuse in hospital settings were included alongside those from residential and nursing homes for two reasons. First because of the limited evidence available about institutional abuse and second because the organisational provision of 24 hour a day, long term care of older people has recently shifted from health to the social care in the UK. There was a 60% reduction in the number of overnight NHS beds for older people 1987-2010 and a 360% increase in the number of places in nursing homes 1985-2005 (Ferlie et al 2013).

Firstly, the review identified the major schools of thought about elder mistreatment to ensure a broad range of disciplinary perspectives were included (Booth cited in Petticrew and Roberts, 2005:72). Secondly a data extraction template was used to identify potential organisational aspects and resultant records were organised into logical categories. The findings were grouped using narrative synthesis (Petticrew and Roberts 2005). The within-study analysis, using content analysis, initially identified ten categories which reduced to five through the cross-study analysis which developed descriptors for five organisational factors associated with institutional abuse – infrastructure, management and procedures, staffing,
resident population characteristics and organisational culture (see Tables 1 below). A supplementary category for macro-structural factors was also created.

The key factors of organisational mistreatment identified through the narrative synthesis were presented to service user and service provider panel groups (subject matter experts) and their responses were used to validate and refine the analysis of findings. There were 9 members of the service user panel, of whom 5 were older people living in care homes and 4 were family carers of older people living in care homes. There were 11 members of the provider panel including 3 care assistants, 2 care coordinators, 1 care home manager, 1 owner and manager of a nursing home, 1 owner and manager of a residential home, 1 owner of a residential home, 1 recently retired care home manager, 1 pharmacist providing medication management training to care home staff. Materials were sent out to panel members in advance of meetings to allow preparation.

The study identified five organisational aspects associated with institutional mistreatment (including abuse, neglect and/or loss of dignity) of older people resident in care homes. The findings are presented below beginning with a brief summary of theoretical perspectives on elder mistreatment before the findings from recent investigation reports are outlined. Each of the organisational factors related to mistreatment in residential care are elaborated.

**Theoretical perspectives on elder mistreatment**

Whilst mistreatment of older people in institutional settings has been relatively under-theorized, certain social science disciplines indicate means of theorizing organisational aspects of the phenomenon. Social science perspectives draw attention to both macro- and micro-sociological factors which would contribute in a systemic way to poor quality care.
Research in the organisation studies tradition highlights how care quality is affected by organisational arrangements and has focused attention on structural arrangements for providing care, illustrating how organisational arrangements can enhance or inhibit an individual’s capacity to care. Alternatively, psychological perspectives have been important in explaining how workers may come to mistreat those who depend upon them (Campbell Reay and Browne 2002). One approach is concerned with individual characteristics of abusers and the abused while the other focuses on the interaction between the abuser and their environment. Sociological approaches focus on arrangements for institutional care provision. They identify a paradox between institutions offering care whilst also appearing to punish age-related dependency. By contrast, social policy perspectives omit societal, structural and organisational factors and suggest that institutional care systems will be inherently benign with abuse occurring as an aberration correctable through regulation and individual reviews (Wardaugh and Wilding 1993). Schiamberg et al. (2011) presented an ecological perspective of elder abuse in nursing homes. This approach argued that abuse occurs in a micro-systemic context. Instead of focusing on individual risk factors, they argue for a study of the dynamic interactions between individual and contextual factors.

In summary, there is little convergence of theoretical work in relation to mistreatment in residential elder care. However, the following section demonstrates common and repeated sets of circumstances which suggest that work in this area would be valuable.

**Contemporary investigations into institutional mistreatment**

In the UK, public inquiries investigate the circumstances surrounding organisational failures such as mistreatment of residents. As such, they provide detailed analyses and offer publically available accounts of the circumstances surrounding these events. A review of UK
investigation reports over a 40 year period found that they highlighted similar, repeated sets of circumstances leading to failures in care (Walshe and Higgins 2002). Moreover, public investigation reports have consistently reported similar sets of circumstances and have made similar recommendations (CHI 2004a, CHAI 2009) [See Note 1] despite fundamental changes to the management, regulation and structure of care services, including the closure of long stay hospitals and the creation of regulatory bodies such as the Care Quality Commission. This repetition of findings is highlighted by the similarity between two reports published 20 years apart. Martin (1984) compared the findings of inquiries into allegations of abuse within hospitals from 1969 to 1980 and identified ten broad themes encapsulating hundreds of findings and recommendations. A subsequent report (CHI 2004a), examining the eleven investigations published between 2000 and 2003, identified eight recurrent themes, namely; severe staff shortages, ineffective risk management, lack of agreed policies, supervision of staff and audit, poor team relationships, inadequate leadership, financial problems and a tendency for the service to be geographically or clinically isolated. In addition to these organisational factors the review of investigations identified risk factors at strategic and national/policy levels, such as, recent restructuring, failure to deal with earlier complaints and low priority services. These reports described repeated sets of social circumstances which relate to organisational arrangements for care provision, without exploring how these factors interacted in long-standing failures of care.

Historically, institutional abuses have tended to be conceived of as ‘isolated events’ and the individuals concerned as ‘rotten apples’ who wilfully or negligently failed in their duty of care. This approach is argued to have drawn attention away from examining organisational and system-wide structures within which such abuses took place (Manthorpe and Penhale, 1999).
The publication of the first public inquiry by the Commission for Health Improvement (CHI) in 2000, marked the beginning of a number of contemporary public inquiries in the UK. We searched CHI and CSCI reports from 2000 onwards as these follow the closure of long stay hospitals, the introduction of the NHS and Community Care Act (1990) and the establishment of new national regulatory bodies. Nine reports were selected because they involved allegations of institutional abuse toward vulnerable adults and older people within in-patient and residential care facilities:

1. Investigation into mistreatment of elderly patients at North Lakeland NHS Trust (CHI 2000:1).
2. Investigation following a police investigation into suspicious deaths of five older people at Portsmouth Healthcare NHS Trust (CHI 2002:vii).
3. Investigation into residential services for people with learning disabilities at Bedfordshire and Luton Community NHS Trust (CHI 2003a).
4. Investigation into the care of older people on Rowan Ward at Manchester Mental Health and Social Care NHS Trust (CHI 2003b:2).
5. Investigation into acute, community and mental health services at Pembrokeshire and Derwen NHS Trust (CHI 2004b).
6. Investigation into care of people with learning disabilities at Cornwall Partnership NHS Trust (CHAI 2006).
7. Investigation at Sutton and Merton NHS Trust in one hospital and three community homes (CHAI 2007).
The findings and recommendations from these investigations indicated repeated institutional failures to properly care for vulnerable adults and older people. They found several commonly-identified problems including an increase in the number of high dependency residents, lack of capability of staff, poor staffing levels, the use of immigrant workers with little command of English and a lack of policy and guidelines and/or their proper implementation and monitoring. What is notable is that seemingly minor or relatively common changes were leading, at times, to spectacular failures of care. Hence, these investigations identified problems and concerns for the way health and social care services were organised and delivered. In addition there were incidents of repeated failure, where one or more people were found to be regularly physically abusing residents, triggering or resulting in the suspension and/or disciplining of particular staff members. The reports recommended the referral of these individual staff members to the national council of nursing for possible competence review of their practice. At Rowan Ward in England and the Leas Cross Nursing Home in Ireland, the facilities were subsequently closed down.

Organisational aspects of mistreatment

Several commonly occurring organisational factors were associated with sustained reduction in care quality: infrastructure, management and procedures, staffing, resident population characteristics and culture. Macro-structural aspects also featured. These factors are elaborated alongside reference to the source material.

1. Infrastructure

Organisational infrastructure refers to the physical environment, building design and architecture, the general upkeep of the building, provisions for catering, cleaning and
maintenance. Table 1 details relevant research and inquiries that identified infrastructure as an important contributor to the circumstances of mistreatment.

[Merge Table 1 here]

Mistreatment of older people took place in residential settings where there were run-down facilities, cramped conditions (Hawes 2003), overcrowding of residents, lack of equipment and generally poor physical environments (Wiener and Kayser-Jones 1990, CHI 2004b). One study concluded that large-sized units promoted regimentation and negatively affected individualised care (Wardhaugh and Wilding 1993). Provisions for catering, cleaning and maintenance that were found to be problematic included poor catering provision and food hygiene (CHAI 2009), unchanged bed linen, strong odours of urine/faeces (Lindbloom et al. 2005), and a lack of privacy with open bathing, toileting and washing (Bennett, Kingston and Penhale 1997). Investigations found that poor conditions in these particular residential settings were recurring problems that had been well documented in the past.

2. Management and procedures

Management, for the purpose of this study, refers to: management arrangements, systems and practices, leadership, supervision, organisation and support of staff. Procedures refer to the systems in place to guide action, including written policies and procedures. Table 1 details relevant research and inquiry reports.
Poor management and/or leadership is thought to play a key role in institutional mistreatment (Bennett, Kingston and Penhale 1997, CHAI 2009, CHI 2004a). Investigations suggested that problems arose over a substantial period of time with little effective response to concerns being raised (CHI 2004a). Problems associated with changes to management included; not having a manager in place, little continuity of management, lack of leadership, poor quality management and lack of a permanent manager in post (CHAI 2006, CHI 2003b). Overly bureaucratic and instructive management styles were associated with mistreatment alongside a lack of investigation into complaints or failure to take actions following the outcome of previous investigations (Wardhaugh and Wilding 1993). A range of inadequate policies were found in five of the investigations, including; policies on complaints, protection, the use of restraint, the management of incontinence, the management of medicines and the provision of palliative care (Bennett, Kingston and Penhale 1997, CHI 2004a, CHAI 2009).

The provider panel highlighted the need for a ‘no blame culture’ for mistakes as mistakes and sub-standard care were more likely to be acknowledged if staff could be sure they would not be blamed individually for the problems. Counterintuitively, members of the service user panel argued that residents would be reluctant to disclose abuse or neglect for fear that their home would close and any alternative could be worse.

Specific additional management problems included unclear lines of accountability (CHAI 2006), the absence of monitoring and supervision of services and staff; absence of staff appraisal and support and poor judgement when recruiting new employees (Buzgová and Ivanová 2009). Furthermore, poor, inconsistent or falsified record keeping was noted as was poor collection and use of information on outcomes of care (CHAI 2009).
The service provider panel group underlined the importance of relationships and argued that the leadership style of managers shaped relationships within the home. They associated respect and dignity with an absence of overly-rigid routine; the provision of on-going training; and access to sources of support for all staff including home managers and owners.

3. Staffing

Factors related to staffing were a commonly-identified theme within research studies, reports and investigations and included; inadequate staffing levels and staff shortages (CHI 2004a), extensive use of temporary or short-term staff (CHI 2003a, CHI 2003b) and high staff turnover (Lee-Treweek 1997). Table 1 shows aspects of staffing associated with mistreatment.

Problems arose where staff worked long hours and were subject to mandatory overtime leading to tired staff (Hawes, Blevins and Shandley 2001), high workloads (Global Action on Aging 2009) and low morale (CHAI 2007). Further problems related to inadequate staff skill mix (Bennett, Kingston and Penhale 1997), limited ability in English language (Wiener and Kayser-Jones 1990) and lack of competency (Teeri, Leino-Kilpi and Välimäki 2006). Some staff were unable to recognise abuse and had negative attitudes towards patients (CHAI 2007). Much of the work in this area identified lack of staff training as an issue (Bennet, Kingston and Penhale 1997, CHAI 2009). Individual characteristics of staff included alcohol dependency (Bennett, Kingston and Penhale 1997), childhood experiences of abuse and high anxiety (Campbell Reay and Browne 2001) and high anger scores (Gates, Fitzwater and Meyer 1999). One source found too much staff autonomy contributing to mistreatment (Bennett, Kingston and Penhale 1997).
The quality of relationships between staff and residents was seen as highly important by both panel groups. They argued that working arrangements such as; the lengths of shifts, the number of people on duty and low staff turnover were all important in sustaining positive relationships. Resident panel members valued being treated as individuals, and also, in return, knowing staff as people with broader lives. For them, the concept of respectful care included sharing some of the responsibility for the day-to-day running of the home.

4. Resident population characteristics

Resident population characteristics associated with mistreatment include the type and level of dependency, complexity of care needs and residents’ own behaviour. Table 1 details resident population characteristics associated with mistreatment.

Residents were at risk where they or their relatives had limited awareness of how to assert their rights and limited access to personal, individual choices (CHAI 2009). Moreover, investigations found that an increase in the proportion of high dependency patients could lead to mistreatment (Buzgová and Ivanová 2009, Commission of Investigation 2009). Specific characteristics associated with mistreatment included residents with high levels of dependency, cognitive impairment or dementia (Burgess, Dowdel and Prentky 2000), physically aggressive or uncooperative behaviour (Buzgová and Ivanová 2009) and passivity, introversion or frailty (Wardaugh and Wilding 1993). Indicators of mistreatment of residents included; unexplained deaths and injuries, dramatic weight loss (Commission of Investigation 2009), untreated or poorly treated pressure ulcers (Pillemer and Bachman-Prehn 1991), oversedation and missing property (Commission of Investigation 2009).
Both service user and provider panels were concerned about happens when the needs of residents change. Residents prefer to stay in the same place whereas staff worry about their ability to provide adequate care. There needs to be a fit between the needs of the group of residents and the adaptability of the home. The review showed that quickly changing levels of need, along with a concentration of people with high levels of need could destabilise the care provision in a home.

5. Culture

Culture refers to practices shaped by shared beliefs and expectations among staff and other groups, which, in turn, produces norms that influence the behaviour of both staff and residents. Table 1 shows the cultural factors associated with mistreatment.

Aspects of culture associated with mistreatment included social or geographical isolation with limited official or social visitors (CHI 2003b). Organisations had closed, inward-looking cultures. Managers and/or staff were institutionalised and closed to possibilities for change (CHI 2004a). There was a focus on external targets, bureaucracy or standardised rather than individual care (Bennett, Kingston and Penhale 1997). This gave rise to overly-bureaucratic or autocratic culture that left staff with little control over their work situation and no say about how work was organised (Buzgová and Ivanová 2009). Poor communication (Wiener and Kayser Jones 1990) and factions among the staff (CHI 2004a) were also features of the local culture. Entrenched routines were seen to objectify residents (CHAI 2009) and there was a lack of renewal of expectations and new ideas (Wardaugh and Wilding 1993).

Service users emphasised contact with the outside community as vital to their wellbeing.

Residential care that involves and supports a good level of integration with the local
community and where there is on-site involvement of allied service providers such as social
workers and doctors were also identified, by panel groups, as factors contributing to respect
and dignity.

6. Macro-structural factors

Macro-structural factors were things that affected the organisation and related to wider social
arrangements for residential care for older people. They are included here as they have a
direct impact on care provision. Table 1 shows macro-structural factors associated with
mistreatment.

Significant organisational changes such as, major structural changes, restructuring, and
changes in ownership were associated with mistreatment (CHI 2004a). Reduced support from
the wider organisation was indicated in one investigation report (CHI 2003b). Financial
pressures were also mentioned frequently, particularly efficiency savings, reduced financial
provisions and lack of resources to provide adequate care (Bennett, Kingston and Penhale
1997). A focus on high profile targets re-directed resources towards meeting targets rather
than the immediate needs of staff and residents (Joint Committee on Human Rights 2007).
Alongside ambiguous accountability arrangements in the wider care community (CHI
2004a), ineffective monitoring by external agencies and failure to challenge punitive care
systems was also cited (CHAI 2006). In addition, there were cases where the nature of the
relationship with overseeing bodies such as an NHS Trust or social services were said to
contribute to the escalation of mistreatment. This included reduction in support and
ineffective monitoring by external bodies (CHI 2003b, CHI 2004a).

Organisational aspects of mistreatment in residential care
Many of the organisational factors associated with mistreatment were found in combinations of two or more factors. This leads us to speculate that these factors are commonly-occurring and potentially inter-dependent. Importantly, small changes could, at certain times, lead to a spiral of declining care. At times, small changes to one factor within a system adversely affected the overall system and the capacity of a home to deliver good quality care. The quality of care was being driven by interactions between individual actors, organisational factors and macro-structural factors.

Systems theory has been used to examine organisations as it allows consideration of interactions and processes with multiple and non-linear effects (Hatch and Cunliffe 2006). The behaviour and actions of all those involved in the organisation (e.g. residents, staff, relatives, owners) and also the context of the organisation (e.g. social, financial, physical) interact dynamically in what could be considered a complex system (Cilliers 2005). Cilliers argues that the system will organise itself to be sensitive to events that are critical to its survival. In other words, relationships between cause and effect are not straightforward and may be either amplified or minimised through dynamic interactions.

There have been several calls for the development of an early warning system to highlight the risk of serious failure (CHI 2004a:2, CHAI 2009:42). This study addresses the fact that ‘there is little or no data on risks to the safety of patients which are not incidents’ (CHAI 2009:32) by enhancing understanding of organisational factors associated with mistreatment (Furnham and Taylor 2011). Further research is needed to develop understanding of interplay between organisational factors.

**Limitations**

There was a limited range of literature available for review and, as discussed above, there is still a lack of widespread consensus on the core concept of mistreatment. We mitigate the limitations to some extent by providing a full account of the knowledge synthesis process and by consulting with
subject matter experts. The findings of this review provide directional indicators for future research and practice.

Conclusions

As an adjunct to personal factors, this knowledge synthesis elaborated five interrelated organisational factors associated with mistreatment of older people in residential settings; infrastructure, management and procedures, staffing, resident population characteristics and culture as well as delineating macro-structural factors. Further research is needed to elaborate the influence of these organisational factors on mistreatment and to understand any interactions.

It was notable that relatively small organisational changes in one or more of these areas could cause care quality to decline rapidly. The practical implication is that care quality is produced systemically and can collapse as a result of seemingly minor and unrelated organisational changes.

It is not enough to close down failing organisations, not least because the inquiry reports alone give powerful accounts of how repeated sets of circumstances led to similar and dramatic failures elsewhere. Understanding the links between organisational factors and care quality is especially important as demand for residential care continue to grow and the availability of funding remains limited.

Statement of ethical approval

The study was reviewed by Cambridgeshire 3 NHS Research Ethics Committee (ref 09/110306/63).

Notes
1. The regulatory body responsible for inspecting NHS organisations has undergone several name changes. Currently known as the Care Quality Commission (CQC), previously known as the Health Care Commission (HCC), Commission for Health Improvement (CHI), Commission for Healthcare Audit and Inspection (CHAI).
