Title:
Knowledge, attitudes and practices of medical staff towards obesity management in patients with spinal cord injuries: an International Survey of four Western European countries

Abstract

Objective: To 1) examine the opinions of medical staff working in spinal cord injury (SCI) centres (SCICs); 2) evaluate their knowledge, attitudes and practices towards obesity prevention and management; 3) report the number of beds and dietitians available at each SCIC.

Methods: A 37-item questionnaire was sent to 23 SCICs in the UK, the Netherlands, Belgium and the Republic of Ireland between September 2012 and January 2013.

Results: Eighteen SCICs returned the questionnaires for analysis. All respondents stated that they had an interest in obesity treatment but only 2.3% of the respondents received training in obesity management. Sixty-one percent of staff did not consider body mass index (BMI) to be appropriate for use in SCI patients and subsequently less than half of the respondents use BMI routinely. The majority of respondents reported that they are confident in dealing with overweight (74.5%) and obese (66.1%) SCI adults, less than half (44.1%) are confident in treating overweight and obese SCI children. Respondents also indicated the need for nationally adopted guidelines and a lack of physical-activity provision. There were 18.6 whole-time equivalent (WTE) dietitians recorded in 22 SCICs, equivalent to 45 beds per WTE dietitians (range 10 – 400). Non-UK SCIC dietitians are significantly better resourced than in UK SCICs (beds per WTE dietitian: 28.9 vs 76.7, p=0.025).

Conclusion: Medical staff expressed the need to participate in obesity prevention and management. Appropriate training should be considered for all medical staff and the development of specific weight management guidelines and dietetic provision should be considered.

Keywords: Obesity management; Spinal Cord Injuries; Staff survey; Weight management
Introduction

Obesity is common after spinal cord injury (SCI). It has become a major clinical and public health problem which requires several medical interventions, modifications of individual behaviour and environmental changes.¹ Recent literatures found that upto 45% of SCI patients were overweight and 29% were obese²³. Obesity is recognised as both a cause and consequence of disease and it has been shown to be associated with poorer clinical outcomes and increased healthcare costs². There are many health risks and associated co-morbidities including hypertension, diabetes, ischaemic heart disease, gallstones, osteoarthritis and some malignancies.¹

Yet in clinical practice, many patients, allied health professionals and hospital managers do not realise how common obesity is in hospitalised patients⁴⁵. If ignored, this will cause a greater problem with the development of chronic nutrition-related complications¹.

Among medical staff, knowledge of, attitudes towards and practices in the management of obesity have been studied in various English-speaking countries, especially amongst General Practitioners (GPs)⁶⁻⁹. However, despite high awareness of obesity as a medically significant issue¹⁰, the magnitude of the obesity epidemic remains high and is worsening, particularly in patients with neurological disabilities such as spinal cord injuries². Weight management is not commonly offered to SCI patients, at least not in the UK¹¹¹².

SCI specialists have been identified as important potential contributors to the prevention and treatment of overweight and obesity, in part, because of continued involvement during rehabilitation. SCI medical staff are therefore in a unique position to provide guidance to patients. In some countries, SCI consultants will continue to see their patients as part of life-long follow up. They are the most frequently used source for information about weight control and are perceived to be the most reliable formal source of information. However to our knowledge, no studies reporting the views of SCI specialists have been published.

A more detailed understanding of knowledge, attitudes and practice is necessary to determine the best way to facilitate the contribution of SCI medical staff in addressing obesity after SCI. Although there are standard published recommendations for SCI management and optimal staffing levels¹³¹⁴, these documents do not make specific recommendations on obesity management.
Whilst dietitians are considered essential members of the multidisciplinary team (MDT) caring for patients with obesity management,\textsuperscript{1,15} the availability of dietitians in British and European SCICs remains variable.\textsuperscript{4}

We therefore conducted this international survey in order to include all the SCICs in four western European Countries including Belgium, the Republic of Ireland, the Netherlands, and the United Kingdom who share similar management approach for SCI care. The aim of the study were: (i) to examine the opinions of weight management among medical staff working in SCICs; (ii) to evaluate their knowledge, attitudes and practices towards obesity prevention and management; (iii) to report the number of dietitians per bed available at each SCIC.

Methods

A 37 item cross-sectional survey was developed based on reviewed literature\textsuperscript{8} and was modified further by a team of multi-disciplinary professionals working in SCICs.

Three, 3, 4 and 5-point scales were used, in which the participants had to indicate their level of agreement with each statement by selecting one from ‘strongly agree’, ‘agree’, ‘neutral’, ‘disagree’ or ‘strongly disagree’; or in practice statements, from ‘very confident’, ‘fairly confident’ or ‘not confident’ and in service statements, from ‘all of the time’, ‘most of the time’, ‘occasionally’ or ‘not at all’.

The questionnaire consisted of five sections; 5 questions on demographic data and staff awareness; 10 statements on exploring attitudes; 3 statements on self efficacy; 11 statements on major limitations and; 8 statements on service improvements.

In addition to gathering baseline demographic data and professional characteristics, a spokesman for each SCIC was asked to provide the number of available SCI beds and the number of whole time equivalent (WTE) dietetic staff.

Because of the small sample size and for ease of presenting the data, most of the responses were grouped together, such that ‘agreed’ encompassed both ‘strongly agreed’ and ‘agreed’, ‘disagreed’ both ‘strongly disagreed’ and ‘disagreed’, and ‘most of the time’ referring to ‘all’ and ‘most of the time’.

Ethics

Formal ethical permission to conduct the study was not required by the Stoke Mandeville hospital review board as this was considered to be a clinical audit not involving active patient participation (NRES).\textsuperscript{16} This was accepted by the other centres.
The questionnaires were approved by the local clinical audit departments for phrasing and grammar of the questions. In addition, a pilot study (n=3) was performed to assess the content and the time required to complete the questionnaire; feedback from this guided the drafting of the final version of the questionnaire (Appendix 1). For Dutch and Belgian participants, the English survey was translated into native language by the study co-author (JvM) and validated by co-authors (ER and IVN) all of whom are competent in both languages (Appendix 2).

Survey administration
The survey was administered to all medical staff working in the SCICs over four European countries (Belgium: n=3, the Republic of Ireland: n=1; the Netherlands: n=8, and the United Kingdom: n=11) between October 2012 and May 2013, with a covering letter addressed to the local medical lead explaining that findings would be used to identify current knowledge, attitude and practices of medical staff and to identify areas for improvement. Participants were reassured that all findings would be treated anonymously and in confidence to encourage respondents to answer honestly. Completed questionnaires were anonymised prior to analysis. Two reminders were sent (one at 8 weeks and one 12 weeks after the initial survey distribution).

Statistical analysis
Descriptive statistics were used to calculate the response frequency. Data are reported as medians (ranges).

Further statistical analysis was conducted to compare the existence of associations between respondents’ demographic and professional characteristics and their survey responses. In addition, the dietetics workforce was compared between UK and non-UK SCICs. For numeric data on an ordinal level, the Mann-Whitney test was used, and for cross-tabulation on a nominal level, the Chi-squared test was performed. The data were analysed using Minitab version 15 (Minitab Ltd, Coventry, UK) and significance was accepted if p<0.05.

Results
Medical staff from 23 SCICs were approached. The centres contained a total of 823 SCI beds (48 in Belgium, 36 in the Republic of Ireland, 258 in the Netherlands, and 481 in the United Kingdom). (Table 1 and Table 2)
The overall SCIC response rate was 78.4% (18/23 SCICs; 59 individual responses, 2-12 responses per SCIC, 63.6% in the United Kingdom (n=7), 66.7% in Belgium (n=2), 62.5% in the Netherlands (n=5) and 100% in the Republic of Ireland (n=1).

Demographics and professional characteristics

Nearly half of the respondents were male (n=26). The median duration of practice in SCICs was 2.5 years. Fifty-four percent (n=32) of respondents were senior doctors/consultants (had completed training) and 67.8% (n=40) were from the UK SCICs. (Table 1)

No junior/trainee doctors reported that they had received formal training in obesity management of SCI patients and only 2 (6.3%) senior doctors reported that they had formal training in this area.

Medical staff attitudes and knowledge towards obesity management

Forty-seven (76%) respondents agreed with the statement, “Obesity is a major health problem amongst patients with SCI and requires urgent action”. Non-UK respondents (100% v 70%, p=0.037) and non-UK consultants (100% v 71.4%, p=0.028) were more likely to agree with the statement than UK respondents. (Table 3)

Most respondents believed that they have a role in obesity prevention (64.5%) and offer advice to their patients (77.9%). Most (86.5%) believed that advice on weight maintenance should be given to all patients with SCI in order to prevent obesity. Most respondents (86.4%) believed that weight management should be offered at an early stage rather than waiting until the patients are obese (18.6%).

Although all surveyed SCICs have dietitian support (Table 3), not all respondents reported that their centre has a dietitian that deals with weight management for SCI patients.

Obesity recognition

Most of the respondents (61%) reported that they do not believe that BMI is an appropriate measure to guide weight management in SCI patients. A minority (35.6%) of the respondents reported they monitor patients’ BMI. In the out-patient setting this is even less common (23.7%). Non-UK respondents were less likely to use BMI
measurements (26.3% v 35.6% in in-patients; 0% v 35% in out-patients) than UK respondents.

Self-reported proficiency / ability

Most respondents felt more confident in treating overweight than obese SCI adults (Table 4). Three out of 4 respondents (74.6%) felt adequately trained to treat patients who are overweight, but only 2/3 (66.1%) of respondents rated themselves competent in managing obesity; fewer than half (44.1%) were confident in treating paediatric obesity, even though most centres were also responsible for the care of children with SCI. (Table 4)

Significantly fewer UK respondents reported being confident in treating obese paediatric patients with SCI than non-UK correspondents (35% v 63.2%, p=0.042, $\chi^2$: 4.144). (Table 3)

Barriers to weight management

The leading five obstacles, identified as limitations in delivering optimal care to obese patients, in descending order, were lack of nationally adopted guidelines (64.4%), lack of patient motivation and non-compliance (61%), lack of provision of a suitable physical activity programme (61%), short consultation time for medical staff (55.9%) and lack of specialist weight management clinics to which to refer patients (52.5%). (Table 5)

There were significantly more UK respondents reported short consultation times to be a limiting factor (70% v 26.3%, p=0.015). Similarly, there were significantly more UK respondents who felt they had inadequate training in providing lifestyle and behavioural counselling for their patients when compared to non-UK respondents (65% v 21.1%, p=0.030).

Weight management strategies

All respondents felt an ideal weight management programme should include dietary advice (100%) and physical activity advice (100%). Leaflets and education material were rated as highly important as preventive measures and in general support. (Table 6)

A large majority of respondents stated that family support (93.2%) and behavioural counselling (88.1%) were important. Most respondents would consider
referred their patients to a dietitian (84.7%) as a first treatment step. Pharmacotherapy and bariatric surgery were the least used strategies, only 6.8% of respondents considered anti-obesity medications, and only 3.4% considered bariatric surgery as an option for weight management.

Dietetic provision in SCICs

The 22 responding centres house a total of 823 SCI beds. There were 18.42 whole-time equivalent (WTE) dietitians recorded; the median of 65.7 beds per WTE dietitian conceals a huge range (from 10 – 400). The workforce allocation is summarised in Table 1. Non-UK SCICs were significantly better resourced than UK SCICs (beds per WTE dietitian: 29.3 vs 76.7, p=0.0322).

Suggestions

Ten out of fifty-nine respondents (16.9%) provided additional feedback. All responses were positive; common suggestions were the need for specific guidelines for weight management and opportunities to attend training.

Discussion

To the best of our knowledge, this is the first international multicentre survey to report on knowledge, attitudes and practices of SCIC medical staff in weight management and on the provisions of dietitians in SCICs. Previous surveys have primarily focused on obesity management among general practitioners and found that practices regarding obesity management vary widely.7–9

Weight gain after SCI is common. This is most likely due to reduced nutritional requirements secondary to enforced inactivity and immobilisation as a result of paralysis and changes in body composition17, most marked in tetraplegia.18 In the long term, there seems to be a tendency for people with SCI to gain weight. Energy needs tend to decrease as a function of time post-injury related to loss of muscle mass. Desirable body weight / BMI for people with SCI may be lower than for the general population.19,20 After SCI, the percentage of body fat increases and muscle decreases. The body composition represented by a fixed BMI will therefore change after SCI. Bucholz’s19 and Laughton’s group20 have showed that BMI in chronic SCI subjects indicates a much higher body fat percentage as compared to age and gender matched able-bodied subjects suggesting further research to define optimal BMI is needed.
All respondents agree that successful weight management should start with prevention. Currently, there are no SCI specific guidelines for prevention and management of overweight and obesity. Generic guidelines published by the UK National Institute for Health and Clinical Excellence (NICE) suggest that dietary and lifestyle changes (a reduction in energy intake, following the eat-well plate set by the government)\(^1\) and increased physical activity in conjunction with behaviour modification support should be considered before any anti-obesity medications or bariatric surgery\(^{20,21}\).

Although weight loss has been advocated as a primary treatment strategy for obesity, to date, little high quality evidence exists to support this concept in patients with SCI. To our best knowledge, only limited trials have reported the effect of dietary interventions in obese SCI individuals. Studies demonstrate that a carefully planned program with restricted dietary intake and lifestyle modification could be an effective way to reduce the body weight of obese patients with SCI without compromising total lean body mass and overall health.\(^{11,12}\)

It is acknowledged that all patients with SCI should receive dietary advice in order to prevent obesity and its complications. In clinical practice, to include all patients would lead to an unmanageable caseload. To offer educational material and input in patient education sessions may be an alternative, more effective and achievable approach. One UK SCIC offers dietetic input for patients with a BMI of 28 kg/m\(^2\) or above and the preliminary data has suggested that this approach has helped overweight individuals with SCI to reduce weight without compromising lean body mass.\(^{12}\)

Dietitians see as their remit the management of factors related to obesity surrounding the physiological, psycho-social and ethnic needs of the patient. Professional guidelines and recommendations offer assistance on how dietitians might improve the quality of care and outcomes.\(^{22}\) To tackle malnutrition and nutrition-related complications, the dietetic practice manual published by the British Dietetics Association has recommended that each SCIC should have access to a specialist dietitian in order to assess patients’ nutritional status and to provide further nutritional advice.\(^{22}\) More recently, the American Dietetic Association has also published guidelines for managing patients with SCI.\(^{24}\) It has emphasised the importance of a specialist dietitian in managing patients in acute, rehabilitation and community settings.

The present study found considerable variation in dietetic provision among SCICs.
varied between centres and British centres has significantly lower dietetic provision when compared to some non-UK centres.

Strengths and limitations

The main strength of this study is that it is the first official international survey conducted in a multicentre European setting which obtained an overall 78.4% response rate from across 4 European countries.

Although the respondent sample size (n=59) was small, we feel this is adequate to reflect the views of SCI doctors working in SCICs. To our knowledge, this represents at least 46.8% of all senior medical staff in the UK and Ireland SCICs (15 out of a total 32) which is comparable to the literature (53% response rate).

Because the centre response rate varied from 2-12 responses per SCIC, some larger centres may be over-represented in the results. In addition, our technique of secondary invitation of respondents by selected lead individuals within a SCIC could introduce selection bias and we acknowledge this; however, guidance was provided to them to circulate the questionnaire to all medical staff, with varying degrees of experience and special interest, working in the SCIC.

There was a predominance of respondents from the UK (n=40) compared to non-UK respondents (n=19). Although this arguably over-represents one country’s perspective, it does not reflect the reality of staff mix in the SCI centres. The numbers of senior medical staff surveyed was comparable in the UK and non-UK centres (14 vs 19).

Conclusion

Limited knowledge among medical staff and variation in dietetic provision in SCIC are probably barriers to effective weight management. Without proper guidelines and training, it is unlikely that healthcare staff will have sufficient knowledge to identify at-risk patients or to offer appropriate treatment. This study reinforces the need to consider collaborating with national professional bodies to develop SCI-specific weight management guidelines which include clear guidance on optimal dietetic service provision within the SCICs.
