Abstract

Background: Fibroblast Growth Factor 18 (FGF18) functions in the development of several tissues, including the lung, limb bud, palate, skeleton, central nervous system, and hair follicle. Mice containing a germline knockout of *Fgf18* (*Fgf18*^{-/-}) die shortly after birth. Postnatally, FGF18 is being evaluated for pathogenic roles in fibrosis and several types of cancer. The specific cell types that express FGF18 have been difficult to identify, and the function of FGF18 in postnatal development and tissue homeostasis has been hampered by the perinatal lethality of *Fgf18* null mice.

Results: We engineered a floxed allele of *Fgf18* (*Fgf18*^{fllox}) that allows conditional gene inactivation and a CreER^{T2} knockin allele (*Fgf18*^{CreERT2}) that allows the precise identification of cells that express *Fgf18* and their lineage. We validated the *Fgf18*^{fllox} allele by targeting it in mesenchymal tissue and primary mesoderm during embryonic development, resulting in similar phenotypes to those observed in *Fgf18* null mice. We also use the *Fgf18*^{CreERT2} allele, in combination with a conditional fluorescent reporter to confirm known and identify new sites of *Fgf18* expression.

Conclusion: These alleles will be useful to investigate FGF18 function during organogenesis and tissue homeostasis, and to target specific cell lineages at embryonic and postnatal time points.

Background

The Fibroblast Growth Factor (FGF) family consists of 18 signaling proteins that regulate embryonic and postnatal development, and in the adult function as homeostatic and tissue repair factors. FGF18 is in the FGF8 subfamily, comprised of FGF8, FGF17, and FGF18 (Itoh and Ornitz, 2008; Itoh and Ornitz, 2011; Ornitz and Itoh, 2015; Ornitz and Marie, 2015). This family of FGFs activate FGFR4 and the mesenchymal splice variants of FGFRs 1, 2, and 3 (Ornitz et al., 1996; Zhang et al., 2006).

Mice containing a germline knockout of *Fgf18* (*Fgf18*^{-/-}) die shortly after birth. The likely deleterious phenotypes include cleft palate, sacular stage lung immaturity, and abnormal nerve terminals in the diaphragm (Ito et al., 2018; Liu et al., 2002; Ohbayashi et al., 2002; Usui et al., 2004). During embryonic development, *Fgf18* primarily signals to mesenchymal tissue in developing bone and cartilage, lung, and brain (Masegawa et al., 2004; Hung et al., 2016; Liu et al., 2002; Liu et al., 2007; Ohbayashi et al., 2002; Usui et al., 2004). The function of FGF18 in postnatal tissue is poorly understood due to the perinatal lethality of the *Fgf18*^{-/-} mouse.

In neonatal rats and mice, *Fgf18* expression increases in the lung during alveologenesis and then returns to lower levels in the adult (Chailley-Heu et al., 2005; Franco-Montoya et al., 2011). Cell sorting experiments

suggest that *Fgf18* is expressed in myofibroblasts of the postnatal lung (McGowan and McCoy, 2015). In skin, *Fgf18* expression is found in inner root sheath cells of the hair follicles where it is thought to maintain stem cells in a quiescent state (Blanpain et al., 2004; Kawano et al., 2005; Kimura-Ueki et al., 2012; Leishman et al., 2013). In adult joint tissue, *Fgf18* is expressed in the articular surface where it is thought to maintain cartilage homeostasis and protect against osteoarthritis (Mori et al., 2014). *Fgf18* is also expressed in the postnatal growth plate (Karuppaiah et al., 2016; Lazarus et al., 2007). In the postnatal brain, *Fgf18* is transiently expressed in neurons in the cerebral cortex and hippocampus (Hoshikawa et al., 2002) and in adult brain tanycytes lining the ventricular wall (Kaminskas et al., 2019).

To facilitate functional studies of *Fgf18* in specific tissues and at postnatal and adult time points we have engineered a floxed allele of *Fgf18* (*Fgf18^{flox}*). Targeting this allele in mesenchymal tissue during embryonic development results in similar phenotypes to those observed in *Fgf18^{-/-}* null mice. To allow the precise identification of cells that express *Fgf18* and to follow their lineage, we have engineered a knockin CreER^{T2} allele, *Fgf18^{CreERT2}*. Activation of fluorescent reporter alleles in embryonic, neonatal, and adult mice confirm known and identify new sites of *Fgf18* expression. These studies validate these novel alleles of *Fgf18* for future functional and lineage studies in mice.

Results & Discussion

Generation of an *Fgf18^{CreERT2}* knockin allele and an *Fgf18^{flox}* allele.

We designed a novel multifunctional targeting vector to generate a conditional (eGFP:CreER^{T2}) lineage tracing allele and knockout (flox) allele from a single gene-targeting event in embryonic stem cells. The allele design was modeled after the design used by the International Mouse Phenotyping Consortium (IMPC) “knockout first” conditional allele (Skarnes et al., 2011), in which the splice acceptor (SA) LacZ was replaced with CreER^{T2}.

The targeting vector design for the *Fgf18* genomic locus placed a splice acceptor (SA)-eGFP:CreER^{T2} fusion gene (Mugford et al., 2008) into the intron located between *Fgf18* exons 1B and 1C, along with a PGK-neo selection cassette (**Fig. 1A**). The SA contains 875 bp of the *En2* intron, the *En2* SA, and 40 bp of *En2* exon 2 (Skarnes et al., 2011). The SA sequence is followed by a T2A sequence and a 15 bp linker sequence placed in frame with eGFP:CreER^{T2}. Integration of the targeting vector into the genome was validated by Southern blot of the 5' and 3' ends (**Fig. 1B, C**).

We strategically included *Frt* and *LoxP* recombination sites in the targeted allele (**Fig. 1D**) to allow the

generation of two independent alleles by crossing the parental mouse line to either a germline expressed FLP recombinase or a germline expressed Cre recombinase mouse (**Fig. 1E, F**) (Farley et al., 2000; Hayashi et al., 2002). This generated a conditional allele, with the critical exon 1C flanked by loxP sites (*Fgf18^{fllox}*) and a tamoxifen inducible eGFP:CreER^{T2} allele driven by the endogenous *Fgf18* promoter (*Fgf18^{CreERT2}*) that can be used for lineage tracing. Importantly, the *Fgf18^{CreERT2}* allele has exon 1C deleted and is predicted to behave as a functional null allele.

Functional testing of the *Fgf18^{fllox}* allele.

We tested the functionality of the *Fgf18^{fllox}* allele by crossing *Fgf18^{fllox/fllox}* mice to *Dermo1^{Cre}* (Twist2tm1.1(cre)Dor) mice to generate *Dermo1^{Cre}; Fgf18^{fllox/fllox}* conditional knockout mice. *Dermo1^{Cre}* targets the mesenchymal condensations giving rise to both osteoblast and chondrocyte lineages (Yu et al., 2003). Like *Fgf18^{-/-}* mice, *Dermo1^{Cre}; Fgf18^{fllox/fllox}* mice are not viable. Analysis of E18.5 *Dermo1^{Cre}; Fgf18^{fllox/fllox}* embryos revealed similar phenotypic features to those observed in *Fgf18^{-/-}* embryos (**Fig. 2A**) (Liu et al., 2002; Ohbayashi et al., 2002). Specifically, *Dermo1^{Cre}; Fgf18^{fllox/fllox}* mice show incomplete suture closure of the calvaria, deformities in the ribs, a bend in the radius, and bowing of the tibia (**Fig. 2B-E**). In contrast to *Fgf18^{-/-}* mice, *Dermo1^{Cre}; Fgf18^{fllox/fllox}* animals do not have a cleft palate defect (data not shown), suggesting this phenotype is due to FGF18 signaling outside of the *Dermo1^{Cre}* targeted mesenchyme lineage. This further suggests that the lethality evident in the *Fgf18^{-/-}* mice is not solely due to a cleft palate defect.

To further examine the effects of widespread FGF18 inactivation within the embryonic mesoderm, we generated *TCre* (Tg(T-cre)1Lwd); *Fgf18^{fllox/-}* conditional knockout mice. *TCre* targets progenitor cells in the primitive streak and tailbud (Perantoni et al., 2005). Like *Dermo1^{Cre}; Fgf18^{fllox/fllox}* mice, *TCre; Fgf18^{fllox/-}* mice were not viable. Analysis of the E18.5 embryos revealed *TCre; Fgf18^{fllox/-}* mice had a distinct hunchbacked appearance (kyphosis) and misshapen limbs (**Fig. 2H, I**; arrows). *TCre; Fgf18^{fllox/-}* phenocopied *Fgf18^{-/-}* mice (**Fig. 2F, G**) (Hung et al., 2016; Liu et al., 2002; Ohbayashi et al., 2002). Heterozygous control mice did not exhibit skeletal defects (**Fig. 2F, H**). Quantification of length of the axis revealed no difference between the germline and conditional knockouts, but both were significantly shorter than their littermate controls (**Fig. 3J**). *TCre; Fgf18^{fllox/-}* conditional knockouts also did not have a cleft palate defect (data not shown). This is presumably due to absence of *TCre* expression in the first and second pharyngeal arches from which the palate is derived. These data suggest that, upon Cre recombination, the floxed allele described here abolishes *Fgf18* activity.

Fgf18^{CreERT2} is a functional null allele.

To determine whether the *Fgf18*^{CreERT2} allele behaves as a functional null allele, heterozygous mice were intercrossed, and homozygous mice were examined at P0 (**Fig. 3**). *Fgf18*^{CreERT2/CreERT2} mice resulted in perinatal lethality. Phenotypic analysis of *Fgf18*^{CreERT2/CreERT2} skeletons displayed abnormalities characteristic of *Fgf18*^{-/-} mice including defects in the jaw, incomplete suture closing of the calvaria, deformities of the ribs, and the characteristic bend in the radius (Liu et al., 2002; Liu et al., 2007; Ohbayashi et al., 2002) (**Fig. 3A-D**). This demonstrates that *Fgf18*^{CreERT2} behaves as a functional null and suggests it can be crossed to the *Fgf18*^{flox} allele to generate heterozygous *CreERT2*^{T2/flox} (*Fgf18*^{CreERT2/flox}) mice, in which *Fgf18*^{CreERT2} can be used to conditionally inactivate the *Fgf18*^{flox} allele. This self-knockout strategy should effectively inactivate *Fgf18* in all *Fgf18*-expressing cells and their lineage descendants when mice are exposed to tamoxifen.

Fgf18^{CreERT2} activity during embryonic development

To determine the expression of *Fgf18*^{CreERT2} and validate its ability to recombine floxed alleles during embryogenesis, we compared the endogenous *Fgf18* mRNA pattern by whole-mount *in situ* hybridization (WISH) (**Fig. 4 A-C**) with the GFP fluorescence pattern of the *Fgf18* driven eGFP:CreERT^{T2} fusion protein (**Fig. 4 D-F**). We then crossed the *Fgf18*^{CreERT2/+} allele with a Cre-dependent *ROSA*^{tdTomato/+} reporter allele to generate *Fgf18*^{Lineage} mice, administered tamoxifen at similar embryonic time points and assayed for recombination mediated tdTomato fluorescence 24 hr later (**Fig. 4G-I**).

Expression of *Fgf18* at E8.0 has been reported in the somites and the presomitic mesoderm (Maruoka et al., 1998). At this stage, weak *Fgf18* expression was observed in the allantois and in a few cells within the emerging first somite (**Fig. 4A**). However, the GFP signal in *Fgf18*^{CreERT2/+} embryos was undetectable, suggesting very low levels of expression (**Fig. 4D**). After inducing at E7.5 and harvesting at E8.5, *Fgf18*^{Lineage} expressing cells were found in the somites (**Fig. 4G**) and in a few cells in the mid-hindbrain junction (mhb) and allantois (data not shown).

At E9.5 *Fgf18* expression displayed a more widespread pattern. As reported (Maruoka et al., 1998), *Fgf18* mRNA was strongly detected in the somites, mhb, and anterior presomitic mesoderm (apsm). Lower levels were detected in the otic pit, trigeminal ganglion, dorsal root ganglia, tailbud, forebrain, and neural tube (**Fig. 4E**). Clear GFP signal was observed only in the somites, mhb, and apsm (**Fig. 4E**). *Fgf18*^{Lineage} expressing cells were observed in the somites and mhb (**Fig. 4H**). Low levels of tdTomato were seen in the forebrain as

well as individual recombined cells in a salt-and-pepper pattern in the tailbud and future jaw, consistent with incomplete recombination (data not shown).

At E12.5, *Fgf18* mRNA was still present in the somites, brain, and apsm. New sites of expression were detected in the future jaw, and in aspects of the limbs (**Fig. 4C**). *Fgf18^{CreERT2}* embryos showed weak GFP signal in the somites, the apsm, the limbs, and the jaw (**Fig. 4F**). *Fgf18^{Lineage}* expressing cells were extensive in the limbs and digits, in the nascent somites, and the jaw (**Fig. 4I**). tdTomato⁺ cells were also present in the interdigit mesenchyme and in tissues in the back of the embryo, consistent with previously reported sites of *Fgf18* expression (Maruoka et al., 1998; Mok et al., 2014). These data suggest that the *Fgf18^{CreERT2}* allele faithfully recapitulates the endogenous expression pattern, however detection of the eGFP:CreERT² fusion protein by native fluorescence is not sensitive enough for lowly expressed tissues or tissues with high autofluorescence.

Fgf18^{CreERT2} lineage during postnatal skeletal development

Fgf18 is expressed in proliferative zone chondrocytes in 1-week-old postnatal rodents and in articular cartilage of adult animals, assayed by qPCR, *in situ* hybridization, and immunofluorescence (Ellsworth et al., 2002; Lazarus et al., 2007; Mori et al., 2014). To identify *in situ* the cells expressing *Fgf18^{CreERT2}* in the postnatal and adult skeleton, *Fgf18^{Lineage}* neonatal mice were injected with tamoxifen and then harvested at different time points for analysis (**Fig. 5 A-C**). In neonatal mice, *Fgf18^{Lineage}* expressing cells were found in the periosteum of cortical bone, the articular surface of the synovial joint, synovial tissue, and in cells within the perichondrial groove of Ranvier. Endosteal *Fgf18^{Lineage}* expression was also observed, but less uniformly compared to periosteal expression (data not shown). The lineage of these *Fgf18^{Lineage}* expressing cells was traced into adult animals (P56) and displayed a similar pattern to the neonatal animals, demonstrating that these cells are maintained. *Fgf18^{Lineage}* animals induced as adults showed tdTomato⁺ cells in the periosteum, articular cartilage, and cells lining the meniscus (**Fig. 5D**).

These studies show that *Fgf18^{CreER}* is active in adult articular chondrocytes indicating that the *Fgf18* gene is expressed in this tissue in adult mice and may therefore have a role in maintaining joint tissue homeostasis or priming the tissue for injury response. These expression data are consistent with immunostaining for FGF18 in rat articular chondrocytes (Mori et al., 2014). Since FGF18 is a secreted growth factor it could act directly on chondrocytes at the joint surface and/or it could be secreted into synovial fluid and signal to any of the tissues lining the joint space.

Fgf18^{CreERT2} lineage in postnatal visceral organ development

In rodent postnatal visceral organ development *Fgf18* expression has been observed in the lung (Chailley-Heu et al., 2005; Franco-Montoya et al., 2011), but its expression in other organs has not been reported. To identify cells expressing *Fgf18* during postnatal visceral organogenesis, *Fgf18^{Lineage}* mice were given daily tamoxifen doses from postnatal day 5 (P5) to P8 and collected on P9. *Fgf18^{Lineage}* expressing cells were detected in the spleen, lung, liver, and pancreas (**Fig. 6**). The bladder, kidney, and small intestine were analyzed but did not display tdTomato⁺ cells. In the spleen, tdTomato⁺ cells were seen in the sub-mesothelial connective tissue capsule (**Fig. 6A**, arrow) as well as sparse cells in the parenchyma. The lung shows the greatest amount of tdTomato⁺ cells, located in the single-cell mesothelium (**Fig. 6B**, arrow) and many cells in the parenchyma (**Fig. 6B**, arrowhead). Cells in the parenchyma were determined to be predominantly alveolar myofibroblasts (data not shown, manuscript in submission). Expression in the liver and pancreas was more restricted with tdTomato⁺ cells located in perivascular regions, likely smooth muscle cells (**Fig. 6C, D**). These results suggest that *Fgf18*, based on expression, has a functional role in postnatal organogenesis of the spleen, lung, liver, and pancreas.

Fgf18^{CreERT2} lineage in adult visceral organ homeostasis

In adult *murine* tissue *Fgf18* expression has been reported in the lungs and kidneys at high levels with lower-level expression in the heart, testis, spleen, skeletal muscle, and brain (Hu et al., 1998). To identify cells expressing *Fgf18* during visceral organ homeostasis, adult *Fgf18^{Lineage}* mice were induced for 1-week with tamoxifen chow followed by a 1-week washout before tissue collection. *Fgf18^{Lineage}* expressing cells were detected in the spleen, heart, aorta, lung, liver, kidney, and cardiac valve (**Fig. 7**). The pancreas, testis, and white visceral fat depot were analyzed but did not show any tdTomato⁺ cells. In the spleen *Fgf18^{Lineage}* labeled cells showed a similar capsule expression pattern as observed in the postnatal animal (**Fig. 7A**), but exhibited additional tdTomato⁺ cells located in the perivascular region around large vessels (**Fig. 7A'**). In the aorta, tdTomato⁺ cells were located in the outermost mesenchymal derived interstitial cells (adventitia) of the vascular wall (**Fig. 7C**). In the heart, lung, liver, and kidney, tdTomato⁺ cells were found, to differing degrees, in visceral mesothelial cells (**Fig. 7B, D, L, K**). The strongest mesothelial expression was seen in the lung followed by the liver. *Fgf18^{Lineage}* cells were found in sparse parenchyma cells in lung and kidney. tdTomato⁺ cells were abundant in cardiac valve interstitial cells (**Fig. 7G**). Taken together these results indicate that *Fgf18^{CreERT2}* is

able to mark diverse cell types in multiple adult organs under homeostatic conditions. Future work to define the fate and function of these cells during injury response should be informative.

Fgf18^{CreERT2} lineage in the adult brain

To gain better insight into the expression of *Fgf18* and cells derived from them in the brain, adult *Fgf18*^{Lineage} mice were induced for two weeks with tamoxifen chow followed by a 1-week washout before tissue collection. Tissue from multiple bregma coordinates was immunolabeled to detect astrocytes (GFAP⁺) as well as *Fgf18*^{Lineage} expressing cells (Tomato⁺) (**Fig. 8**). *Fgf18*^{Lineage} expressing cells were detected in hypothalamic tanycytes and the ependymal lining of the dorsal third ventricle (3V) (**Fig. 8F**). *Fgf18*^{Lineage} expressing cells were additionally detected in a subset of cortical pial astrocytes (**Fig. 8B**); in rare neurons in the cerebral cortex (**Fig. 8C, D**); the choroid plexus, and ependymal lining of the dorsal third ventricle (3V) and fourth ventricle recess (4V) (**Fig. 8E, H**); pial astrocytes (**Fig. 8G**); septum (**Fig. 8J**), and amygdala (not shown). Interestingly, *Fgf18*^{Lineage} expressing cells were also found in the walls of the lateral ventricles. These could be followed anteriorly into the olfactory bulbs, where *Fgf18*^{Lineage} expressing olfactory bulb (OB) neurons were clearly evident, reminiscent of neuronal supply to the OB via the rostral migratory stream (**Fig. 8J, L-O**) (Obernier and Alvarez-Buylla, 2019). In these mice, it is likely the long period between initial tamoxifen treatment and tissue collection resulted in the *Fgf18*^{Lineage} expressing cells including both cells expressing *Fgf18*^{CreERT2} as well as their descendants at the time of harvest. This conclusion is supported by a more restricted number and distribution of *Fgf18*^{Lineage} labeled cells in the hypothalamus of animals pulsed more briefly with tamoxifen and harvested acutely (Kaminskas et al., 2019).

Conclusion

This study demonstrates the generation and validation of two novel alleles targeting the *Fgf18* locus that will be useful for the investigation of the tissue specific function of the gene (*Fgf18*^{flox}) and the lineage of its expressing cells (*Fgf18*^{CreERT2}). Using *Fgf18*^{flox}, it was confirmed that the majority of the skeletal phenotypes of *Fgf18*^{-/-} animals, including deformities of the calvaria, ribs, hindlimb, forelimb, and axis, are dependent on *Fgf18* expression originating from the mesenchymal compartment. Using *Fgf18*^{CreERT2}, expression of *Fgf18* was confirmed in known and identified in new sites in the embryo in multiple organs including the somites and mid-hindbrain junction; the postnatal and juvenile skeleton; in postnatal and adult visceral organs; and in adult brain. These tools will be useful to investigate FGF18 function during organogenesis and tissue homeostasis,

and to target specific cell lineages at various embryonic and postnatal time points.

Experimental Procedures

Animals

All animals were housed in pathogen-free barrier facilities. All studies were performed under a protocol approved by the Institutional Animal Care at Washington University in St. Louis (Approval No. 20160013) or in accordance with the recommendations in the Guide for Care and Use of Laboratory Animals of the National Institutes of Health under a protocol approved by the Animal Care and Usage Committee of NCI-Frederick (NIH) (Animal Study Proposal: 17-069). Mice of both sexes were utilized. Mice were maintained on a mixed C57BL/6J x 129X1/SvJ or outbred genetic background. *Fgf18*^{CreERT2} mice and *Fgf18*^{flox} were generated in house. *Fgf18* allele was generated by recombining the *Fgf18*^{flox} allele in the germline with Sox2-Cre (Hayashi et al., 2002).

All other mouse strains, including, *ROSA*^{tdTomato}, *Dermo1*^{Cre}, *TCre*, Sox2-Cre, and *FLPeR* have been previously described (Farley et al., 2000; Hayashi et al., 2002; Madisen et al., 2010; Perantoni et al., 2005; Yu et al., 2003). Postnatal day 0 (P0) was assigned as the day of birth. Embryonic day 0.5 (E0.5) was assigned as the day the vaginal plug was found in timed-mating experiments. Adult mice were 8 weeks of age or older.

Genetic crosses

To generate *Fgf18*^{-/-} fetuses, *TCre*^{+/+}; *Fgf18*^{-/+} mice were intercrossed. To generate *TCre*⁺; *Fgf18*^{flox/-} mice, *Fgf18*^{flox/flox} females were crossed to *TCre*^{+/+}; *Fgf18*^{-/+} males. Mice were maintained on an outbred background. The *TCre* line has been described previously (Perantoni et al., 2005). To investigate the effectiveness of Cre mediated recombination, we generated *Fgf18*^{CreERT2/+}; *ROSA*^{tdTomato/tdTomato} males and mated them to females to generate experimental litters. This cross was used to assess both GFP signal and Cre-mediated recombination. *Fgf18*^{CreERT2/+}; *ROSA*^{tdTomato/+} when exposed to tamoxifen are referred to as *Fgf18*^{Lineage} mice.

Southern Blot

Genomic DNA digested with *SpeI* was screen by DNA analysis with probes designed against the 5' end and generated by PCR amplification (Probe A: Forward, gctgaatatgttcagatcttgctctgtgc; Reverse, cacaggtggtagcagatgcagcatgatac). Genomic DNA digested with *NdeI* was screen by DNA analysis with probes

designed against the 3' end and generated by PCR amplification (Probe B: Forward, tgtgagtattctgaatgactgtgggtccac; Reverse, gacagccagctcatgtgctcatgatgtctg).

Sample Preparation: Skeleton

Skeletons were prepared as described previously (Colvin et al., 1996; Nagy et al., 2003). For postnatal day P0 skeletal preparations, carcasses were skinned and eviscerated, and then soaked in acetone for 12–24 hr, cleared in 2% KOH (12–24 h), stained with alizarin red S (Millipore-Sigma, 58005) and alcian blue (Millipore-Sigma, 74240) for 12–24 h, cleared in 1% KOH/20% glycerol, and stored in glycerol. For embryo skeleton preparations, fetuses were skinned and eviscerated, stained with alizarin red S and alcian blue (12–24 hr), cleared in 1%KOH/20% glycerol, and stored in glycerol.

Sample preparation: visceral organs

At designated collection times, mice were sacrificed with an overdose of a cocktail containing ketamine and xylazine, perfused with PBS through the right ventricle, and indicated organs were fixed with submersion in 10% neutral buffered formalin (VWR International, Radnor, Pennsylvania; 89370). Lungs were fixed via intratracheal inflation at a pressure of 20 cm H₂O of 10% neutral buffered formalin. Organs were fixed overnight at 4°C with gentle agitation. Samples were washed twice in PBS, cryoprotected in 15% sucrose in PBS overnight at 4°C with gentle agitation, and then 30% sucrose overnight at 4°C with gentle agitation. Organs were patted dry, equilibrated in Tissue-Tek® O.C.T. compound (VWR, 4583) for 20 min, embedded, and frozen on dry ice. Frozen sections were cut at 6 µm with a cryostat, dried at room temperature, and stored at -80°C until use. Slides were warmed for 10 min at room temperature and washed in PBS before being permeabilized in PBS + 0.5% Triton X-100 (Sigma, X-100) for 15 min. Slides were washed 3x in PBS, mounted in Vectashield® antifade mounting medium with DAPI (ThermoFisher, NC9524612), sealed with nail polish, and stored at 4°C until imaged.

Tamoxifen administration

For embryonic experiments tamoxifen (80 mg/kg) and progesterone (40 mg/kg) were co-injected intraperitoneally (IP) into pregnant dams 24 hours before collection of embryos. To prepare, 100 mg of tamoxifen (Millipore-Sigma, T5648) was dissolved in 5 ml of corn oil (Millipore-Sigma C8267) to which was added 5 ml of 50 mg/ml progesterone dissolved in sesame oil (Watson Pharma Inc., Parsippany, New Jersey;

NDC 0591-3128-79). This was then sterilized through a 0.22 μm filter and stored at 4°C before use. For early neonatal experiments, tamoxifen was administered by IP injection at a dose of 150 μg on four sequential days beginning at postnatal day 5 (P5). Tamoxifen was prepared at a concentration of 20 $\mu\text{g}/\mu\text{l}$ dissolved in corn oil or sunflower seed oil for injection. For juvenile and adult experiments tamoxifen was administered by chow (400 mg/kg tamoxifen citrate) (Envigo, Huntingdon, United Kingdom; TD.130860) for 10-14 days (juvenile), 7 days (adult visceral organs), or 14 days (adult skeleton). Tamoxifen was administered by chow in longer-term juvenile and adult experiments to avoid unnecessary injections (Whitfield et al., 2015). IP injections were unavoidable in embryonic and neonatal experiments. Differences in recombination efficiency between the two methods of tamoxifen administration were not directly assessed.

In situ hybridization

Whole mount *in situ* hybridization was performed according to published protocols (Wilkinson and Nieto, 2003). The *Fgf18* probe was generated from a previously published plasmid linearized with SacII and transcribed using SP6 polymerase (Xu et al., 2000). Prolonged development of the stain was required for E8.0 embryos. Samples at E9.5 and E12.5 were cleared in 50% glycerol:PBS for several days prior to imaging.

Imaging

With the exception of adult brain analysis, eGFP and tdTomato were detected by native fluorescence. Images are representative of at least 2 mice. For brain analysis, serial 60 μm thick coronal vibratome sections were generated and immunolabeled with anti-Tomato dsred as well as anti-Glial Fibrillary Acidic Protein (GFAP) antibodies, performed according to published protocols (Haan et al., 2013; Kaminskas et al., 2019). Immunolabelled sections were counterstained with Hoechst stain. Atlas images are from the Mouse Brain Library (http://www.mbl.org/mbl_main/atlas.html) (Williams, 2000).

Fluorescent microscopy of slides was performed using either Zeiss LSM-700 Confocal Microscope Carl Zeiss AG, Oberkochen, Germany) (single plane) and or on a Zeiss Axio Imager M2 with respective ZEN software. Differential interference contrast microscopy of slides was performed using Zeiss Axio Imager M2. Whole-mount brightfield images were performed using an Olympus SZX12 Stereozoom microscope (Olympus Corporation, Tokyo, Japan) or Olympus MVX10 microscope. Whole mount fluorescent images were performed using an Olympus MVX10 microscope excited using an X-Cite Turbo XT600-T fluorescence light source (Excelitas Technologies Corp, Waltham, Massachusetts) at 475 nm and 575 nm wavelengths. Images were

processed using either Canvas X (Canvas GFX), ImageJ, or Photoshop (Adobe Inc., San Jose, California).

Measurements, Statistical Analysis, and Plotting

Length of the axis was measured from the atlas to the tip of the tail. Data were found to be normally distributed by a Shapiro-Wilk test. Significant differences in mean values between two sets of data were calculated by using an unpaired t-test. A P value of less than 0.05 was considered significant. Sample size (n) represents the number of animals. Data are represented as mean \pm standard deviation. * indicates $p < 0.05$. All figures were made in Canvas X. Plots were generated in Prism 7 (GraphPad Software, San Diego, CA).

Figure legends

Figure 1

Generation and validation of the *Fgf18^{CreERT2}* and *Fgf18^{flox}* mouse lines. **A**: Scheme displaying targeting vector design and insertion into the *Fgf18* genomic locus. **B, C**: Southern blot analysis of the *Fgf18* targeted allele, with DNA digested with *SpeI* (left) or *NdeI* (right) in WT and het animals. Probes were amplified by PCR from indicated regions. **D**: Scheme of the successfully inserted intermediate targeted allele. **E, F**: Scheme displaying generation of a conditional allele (*Fgf18^{flox}*; **E**) and a tamoxifen-inducible eGFP:CreER^{T2} lineage allele (*Fgf18^{CreERT2}*, **F**) by crossing the targeted allele to germline expressed FLP recombinase and CRE recombinase, respectively. Pink arrows indicate LoxP sites; Red bars indicate FRT sites; Green bars indicate eGFP:CreERT2-pA cassette; Blue bars indicate PGK-neo-pA cassette. WT=wild type; Het=*Fgf18^{Targeted allele/+}*

Figure 2

Recapitulation of known skeletal phenotypes upon removal of *Fgf18* using the *Fgf18^{flox}* allele. Alizarin red and Alcian blue stained whole skeleton of E18.5 mice following mesenchyme specific *Fgf18* inactivation with *Dermo1^{Cre}* (**A-E**) or *TCre* (**F-I**). **A-E**: Top, *Fgf18^{flox/flox}* controls; Bottom, *Dermo1^{Cre}; Fgf18^{flox/flox}* conditional knockouts. Skeletal defects are seen in (**A**) whole skeleton, (**B**) calvaria, (**C**) ribs, (**D**) forelimb, and (**E**) hindlimb. Arrows indicate a characteristic bend in the radius and bowed hindlimb zeugopods. **F, H**: controls, (*TCre; Fgf18^{+/+}*, *TCre; Fgf18^{flox/+}*, respectively), **G**: homozygous *Fgf18* knockout (*TCre; Fgf18^{-/-}*), **I**: mesenchyme specific inactivation of *Fgf18* (*TCre; Fgf18^{flox/-}*). Arrows indicate kyphosis, bend in the radius, and bowed hindlimb zeugopods. **J**: Quantification of the length of the axial skeleton in *TCre; Fgf18^{+/+}*, *TCre; Fgf18^{-/-}*, *TCre; Fgf18^{flox/+}*, and *TCre; Fgf18^{flox/-}* animals. Student's t-test, * $p < 0.05$. Error bars, mean \pm SD. n=5 (*TCre; Fgf18^{+/+}*, *TCre; Fgf18^{-/-}*), n=3 (*TCre; Fgf18^{flox/+}*), n=6 (*TCre; Fgf18^{flox/-}*).

Figure 3

Validation that *Fgf18^{CreERT2}* behaves as a functional null allele. **A-D**, Alizarin red and Alcian blue stained whole skeleton of P0 *Fgf18^{CreERT2/CreERT2}* and control (*Fgf18^{CreERT2/+}*) mice showing defects in (**A**) jaw, (**B**) calvaria, (**C**) ribs, and (**D**) limbs. Arrow indicates a characteristic bend in the radius.

Figure 4

Fgf18^{CreERT2} expression in during embryogenesis. **A-C**: Whole-mount *in situ* hybridization (WISH) for *Fgf18* mRNA in E8.0 (**A**), E9.5 (**B**), and E12.5 (**C**) wild type embryos. **D-F**: Whole mount eGFP fluorescence in E8.0 (**D**), E9.5 (**E**), and E12.5 (**F**) *Fgf18^{CreERT2/+}* embryos. Note: The *Fgf18^{CreERT2}* allele contains an eGFP fused upstream of CreER^{T2}. **G-I**: Whole mount tdTomato fluorescence of mice induced 24 hr before collection at E8.5 (**G**), E10.5 (**H**), and E13.5 (**I**) in *Fgf18^{CreERT2/+}; ROSA^{tdTomato/+}* embryos. All embryos are shown laterally and are of the stage indicated. Arrows and brackets indicate localized expression. a, allantois; apsm, anterior paraxial somitic mesoderm; dc, digit condensation; dr, digit ray; drg, dorsal root ganglion; fb, forebrain; fe, femur; lc, limb bud; lpc, limb paddle condensation; lj, lower jaw; mhb, mid-hindbrain; nt, neural tube; op, otic pit; s, somite or somites; tb, tailbud; tg, trigeminal ganglion.

Figure 5

Fgf18^{CreERT2} expression in skeletal tissue. **A-C**: *Fgf18^{CreERT2/+}; ROSA^{tdTomato/+}* lineage mice were injected with tamoxifen daily from P5 to P8 and were collected at P9 (**A-A'**), P21 (**B, B'**), or P56 (**C, C'**) and imaged for tdTomato epifluorescence and histology using differential interference contrast (DIC) microscopy. tdTomato epifluorescence was observed in the periosteum (**A, B, C**), articular surface (**A', C'**), meniscus (**A''**), and the groove of Ranvier (**B', asterisk**). **D**: *Fgf18^{CreERT2/+}; ROSA^{tdTomato/+}* lineage mice were given tamoxifen chow at 8 weeks of age for 14 days and collected at 12 weeks of age. tdTomato epifluorescence and DIC (grey) microscopy showing tdTomato⁺ cells in the periosteum (**D**) and articular surface (**D'**). Arrow indicates tdTomato⁺ cells in the periosteum. Arrowhead indicates tdTomato⁺ cells at the articular surface. ac, articular chondrocytes; bm, bone marrow; ct, cortical bone; gp, growth plate; m, meniscus; mu, muscle; p, periosteum; sb, subchondral bone; s, synovium; tb, trabecular bone. * indicates groove of Ranvier. Scale bar, 100 μ m.

Figure 6

Fgf18^{CreERT2} expression in postnatal visceral organs. **A-D**: *Fgf18^{CreERT2/+}; ROSA^{tdTomato/+}* mice were injected with tamoxifen daily from P5 to P8 and were collected at P9. tdTomato⁺ expressing cells include: (**A**) splenic capsule (arrow); (**B**) pulmonary mesothelial cells (arrow) and alveolar mesenchyme (arrowhead); (**C**) liver and (**D**) pancreas perivascular cells (arrows). Bd, bile duct; pv, portal vein. Dapi (Blue). Scale bar, 100 μ m.

Figure 7

Fgf18^{CreERT2} expression in adult visceral organs. **A-G:** *Fgf18^{CreERT2/+}; ROSA^{tdTomato/+}* mice were given tamoxifen chow at 8 weeks of age for 7 days and collected at 10 weeks of age. tdTomato⁺ expressing cells include: (**A, A'**) splenic capsule (arrow) and perivascular (arrowhead) cells; (**B**) select epicardial cells (arrow); (**C**) aorta interstitial cells in the vascular wall (arrow); (**D**) pulmonary mesothelial (arrow) and alveolar interstitial cells (arrowhead); (**E**) hepatic mesothelial cells (arrow); (**F**) kidney mesothelial cells (arrow) and occasional epithelial tubule cells (arrowhead); (**G**) cardiac valve interstitial cells. Dapi (Blue). Scale bar, 100 μ m.

Figure 8

Fgf18^{CreERT2} expressing cells and their putative descendants in the adult brain. *Fgf18^{CreERT2/+}; ROSA^{tdTomato/+}* mice were given tamoxifen chow at 9 weeks of age for two weeks and collected at 12 weeks of age. **A, I, K:** Photomicrographs from brain atlases to aid regional visualization. **B-H, J, L-O:** tdTomato⁺ expressing cells include: GFAP⁺ astrocytes of the Glia limitans (**B-B''**); rare non-pyramidal (**C**) and pyramidal cortical neurons (**D**), ventricular ependymal cells, adjacent to the medial habenula (**E**), with no expression in the hippocampus; hypothalamic tanycytes and sparse ependymal cells of the third ventricle (3v) wall (**F**); pair of GFAP⁺ pial astrocytes (**G-G'**); strong and specific expression in the choroid plexus of the fourth ventricle's (4v) lateral recess (**H**), near the cerebellum; medial and lateral walls of the lateral ventricles and rare septal neurons (**J, J'**), shown in hemisection; anterior olfactory bulbs (**L, L'**), near rostral migratory stream cells; scattered neurons in the anterior olfactory cortex (**M-O**). Arrows and arrow heads in (M, N) indicate tdTomato⁺ neurons and their neurite trajectory. Lines indicate structures. Scale bars: 100 μ m in B, C, D, E, F, J and L; 50 μ m in B', G and L'; 25 μ m in G' and M-O. v, ventricle; h, hippocampus; cp, choroid plexus; m.e., median eminence; hb, habenula. Atlas images are from the Mouse Brain Library (http://www.mbl.org/mbl_main/atlas.html).
